Sentiment Analysis For Stock Price Prediction

Idea: We use NLP to extract information and news about certain companies for sentiment analysis to predict the stock market to maximize investment gains.

Process:

- 1. Data retrieval
 - a. Fetch the articles using RapidAPI's NewsNow and Google news endpoints
 - b. Limit the amount of articles from one publisher to get unbiased results

2. Data Pre-processing

- a. We divide each of the articles into a list of paragraphs and sentences
 - i. Each paragraph corresponds to the list of sentences through the index
- b. document structure -> document = {[url]: {'paragraphs': [], 'sentences': [[], [], ...]}}
- c. We use the nltk corpus stopwords to remove unnecessary articles or words that can hinder the sentiment scoring and only store alphanumeric characters from the text
- d. We also use a lemmatizer from TextBlob's Word lemmatizer for further refinement

3. Sentiment analysis

- a. Give nltk's Vader (Valence Aware Dictionary and sEntiment Reasoner) module our pre-processed data
- b. For every document, we go through the article paragraph by paragraph and append each of their sentiment scores to a list.
- c. After iterating through all the paragraphs in the list, we average the sentiment scores of all the paragraphs to obtain a reasonable and final sentiment score for the document to determine if the article has a positive or a negative connotation about the subject of interest.

4. Final Decision

- a. After computing all the sentiment scores for a specific Company, check if its score is above or below a specific threshold to buy/sell/hold the stock
- b. Threshold numbers could be anything above 0.2 buy, below -0.2 sell, and between hold

Results & Comparison:

- 1. Stemmer vs Lemmatizer
- 2. Removing stop words vs keeping them.
- 3. Calculating sentiment scores using two different methods:

Sankalp Shubham - sxs190290 Daniel Kadosh - dxk220045

- Taking an average of each sentence sentiment score and then determining the paragraph sentiment through that. Then finally averaging the sentiment scores of all the paragraphs to determine the sentiment score of the entire document. (Lower performing scores)
- b. Averaging the scores of the paragraphs and skipping sentiment analysis on the sentence individually. (Better performing scores)

Outputs:

Sentiment Output on an article about recent nationwide protesting:

```
[21] clean_text2(article.maintext)

'protest roiling college campus nationwide administrator graduation ceremony next month face dema sted saturday campus including indiana university arizona state university washington university university arrested demonstrator april sign solidarity seen protest columbia university campus not ampment around prompting range response arrest criminal student suspension simply continued plea ion legal record follow student adult faculty member university georgia texas initiated passed la joe biden strong would leave ma...'
```

```
[22] sid.polarity_scores(clean_text2(article.maintext))
{'neg': 0.242, 'neu': 0.672, 'pos': 0.086, 'compound': -0.9992}
```

```
    positive sentiment: compound score >= 0.05
    neutral sentiment: (compound score > -0.05) and (compound score < 0.05)</li>
    negative sentiment: compound score <= -0.05</li>
    NOTE: The compound score is the one most commonly used for sentiment analysis by most researchers, including the authors.
```

Disclaimer: Usually not the case on big articles

Compound is calculated by summing all the lexicon ratings which have been normalized between -1 and +1

Future Implementations:

- 1. Identifying more areas to improve scoring
 - a. example: avoiding company news websites, finding more diverse news outlets
 - b. remove news outlets that can't be processed correctly
- 2. Adding the Gemini model for final analysis for final decision making
